## The Normal Distribution

If you take a large sample of
What is it? measurements from a con 1 UQOUS $r \underline{a} n d t m v a r \perp a \underline{b} L \underline{e}$ in a population, a histogram of this data will look be $1 \perp$ shaped.

The probability distribution curve for these data can be approximated using a formula for the normal distribution.

Two pieces of information are required by the formula: the pop $\underline{\sim} \leq \underline{u} \pm \perp \underline{2}$ mean and the $p \propto q \underline{u} \perp \underline{a} \perp \perp \underline{Q}$ standard deviation.

## Notation

$\boldsymbol{\mu}$ Population mean
$\sigma$ Population $S t a n d a r d$ deviatLOA
$\bar{x}$ Sample mean
$s$ Sample Sta $\square d$ a $\operatorname{cd}$ devta土ıon

## Empirical Rule

(68-95-99.7 Rule)

Most data is near the middle and there is less data as you move away from the middle towards the tail
$\underline{6} 8 \%$ of the data are within 1 standard deviation of the mean $95 \%$ of the data are within 2 standard deviations of the mean $99.7 \%$ of the data are within 3 standard deviations of the mean

The Curve

Symme $\pm \angle \perp C$ about the mean
The shape is determined by two
pargmeters
$\rightarrow \boldsymbol{\mu}$ - where the middle is
$\rightarrow \boldsymbol{\sigma}$ - how wide and tall it is
We often don't know these p arameters so we have to estimate them using $\bar{X}$ and $S$, ideally from a sample $>30$

## The Normal Distribution

## The Area Under the Curve

The area under the curve represents the probab $\perp$ Lity of all possible outcomes. The total area under the curve is therefore equal to one $(\underline{O} \underline{O} \%)$

We can work out the percentage of data that lie within a given range of values using:

1) The Empirical Rule
2) az-table $\rightarrow$ calculator
3) a statistical software package

## Practice

On a standardized exam, the scores are normally distributed with a mean of 170 and a standard deviation of 20. Find the $z$-score of a person who scored 140 on the exam.

$$
\begin{aligned}
& z=\frac{140-170}{20}=\frac{-30}{20}=-\frac{3}{2} \\
& z=-1.5
\end{aligned}
$$

the scove of 140 is 1.5 standard devlations bel ow the mean

## Z-Scores

- A numerical value that tells you how far a value ( $x$ ) is from the mean. It measures distance in terms of standard deviation.
- For example, a z-score of 2 means that the value $(x)$ is 2 standard deviations above the mean.
- Z-scores are used to calculate these percentages.
- A z-score (z) is calculated using:

$$
z=\frac{x-\mu}{\sigma}
$$

## Real World Examples

Data collected on many
natural phenomena, such as
$b e l g h t$ and $W e \perp g h t$ of people, have an approximate normal distribution.

These data are typically influenced by many factors and no single factor overpowers the others.
